L4 ANSWER 3 OF 7 AGRICOLA Compiled and distributed by the National Agricultural Library of the Department of Agriculture of the United States of America. It contains copyrighted materials. All rights reserved.
(2003) on STN DUPLICATE 1

AB **Transgenic plants** overexpressing the vacuolar H(+)-**pyrophosphatase** are much more resistant to high concentrations of

NaCl and to water deprivation than the isogenic wild-type strains. These **transgenic plants** accumulate more Na(+) and K(+) in their leaf tissue than the wild type. Moreover, direct measurements on isolated vacuolar membrane vesicles derived from the AVP1 **transgenic plants** and from wild type demonstrate that the vesicles from the **transgenic plants** have enhanced cation uptake. The phenotypes of the AVP1 **transgenic plants** suggest that increasing the vacuolar proton gradient results in increased solute accumulation and water retention. Presumably, sequestration of cations in the **vacuole** reduces their toxic effects. Genetically engineered drought- and salt-tolerant **plants** could provide an avenue to the reclamation of farmlands lost to agriculture because of salinity and a lack of rainfall.

- L4 ANSWER 4 OF 7 CAPLUS COPYRIGHT 2003 ACS on STN
- AB A review. Development of genetically modified **plants** is crit. for stable food supply in future. However, spread of the artificially created phenotype out to ecosystem through the pollen of the **plant** is a major concern. Therefore, rendering male sterility to the pollen is another important objective in developing the genetically modified **plants**. The authors had identified a promoter segment of the gene encoding **vacuole inorg. pyrophosphatase** (V-PPase) gene of *Arabidopsis thaliana* that could activate the gene in a pollen-specific manner. Upon introduction of the V-PPase gene antisense oligonucleotide attached with the promoter segment to the **plant**, 3-5 % of the next generation became remarkably sterile without developing fruits and 10-20 % became significantly reduced fertility although they had fruit development. The authors concluded the pollen specific promoter segment would be a very useful tool applicable to various **plant** genes if the copy no. of the transgene could be increased. In addn. to choosing better target cells of diploid than the haploid pollen cells for increasing copy no., use of RNA interference technol. was described as an alternative to the antisense technol. to improve the repression efficiency.

L4 ANSWER 6 OF 7 CAPLUS COPYRIGHT 2003 ACS on STN DUPLICATE 2
AB In order to assess the contribution of increased leaf osmolality to
plant frost hardiness, **transgenic** tobacco (*Nicotiana*
tabacum) **plants** that accumulate sol. carbohydrates were used.
The leaves from **plants** of the clone U-pps-1-10 expressing a
bacterial **pyrophosphatase** gene displayed an increase in frost
hardiness of 1.2.degree. when compared with wild type control
plants. Most strikingly, these **plants** showed a higher
capacity to increase their hardiness during exposure to 4.degree. growth
temp. for 10 to 14 days; frost hardiness increased by 1.1.degree. in
transgenic plants as compared with 0.2.degree. in wild
type controls. Of the other three independent clones transformed with the
pyrophosphatase gene, none showed a statistically significant
increase in hardiness compared with wild type **plants**, or
increased hardiness after cold acclimation. There was no correlation
between leaf osmolality and hardiness when leaves from cold acclimated and
from non-acclimated wild type and all clones of transformed tobacco were
compared. Tobacco **plants** expressing an apoplastic yeast
invertase gene were more susceptible to freeze-thaw stress than wild type
controls, in spite of increased leaf osmolality due to sugar accumulation
in the leaf cells. Cold acclimation of such **plants** resulted in
increased frost hardiness, which, however, did not exceed the hardiness of
untransformed controls. When the expressed invertase gene contained a
signal sequence for targeting the protein to the **vacuole** only
moderate increases in leaf osmolality were obtained. None of the three
independent clones investigated showed improved frost hardiness compared
with the wild type.

(2003) on STN DUPLICATE 3
AB Photosynthetic characteristics of **transgenic** tobacco (*Nicotiana*
tabacum L.) **plants** with a soluble **pyrophosphatase** in
the cytosol of their leaf cells were compared to those of wild-type
plants. Although the development of the **transgenic**
plants was somewhat retarded compared to the wild type, as shown

by stunted growth and delayed flowering, photosynthetic responses were comparable in **transgenic** and wild-type leaves of similar physiological age. In particular, light-dependent proton transport into the vacuoles of leaf mesophyll cells was not decreased in leaves of the **transgenic plants**, which did not contain pyrophosphate in the cytosol owing to the presence of a soluble pyrophosphatase. This shows that light-stimulated proton pumping did not require the pumping activity of the **tonoplast pyrophosphatase**. Apparently, light-stimulated proton pumping can be based solely on the activity of the **tonoplast ATPase**.

=> d 4 ab

L6 ANSWER 4 OF 42 CAPLUS COPYRIGHT 2003 ACS on STN DUPLICATE 1

AB As in many other fleshy fruits, the predominant org. acids in ripe peach (*Prunus persica* (L.) Batsch) fruit are malic and citric acids. The accumulation of these metabolites in fruit flesh is regulated during fruit development. Six peach fruit-related genes implicated in org. acid metab. (mitochondrial citrate synthase; cytosolic NAD-dependent malate dehydrogenase, and cytosolic NADP-dependent isocitrate dehydrogenase) and storage (vacuolar proton translocating pumps: one vacuolar H⁺-ATPase, and two vacuolar H⁺-pyrophosphatases) were cloned. Five of these peach genes were homologous to genes isolated from fruit in other fleshy fruit species. Phylogenetic and expression analyses suggested the existence of a particular vacuolar **pyrophosphatase** highly expressed in fruit. The sixth **gene** was the first cytosolic NAD-dependent malate dehydrogenase **gene** isolated from fruit. **Gene** expression was studied during the fruit development of two peach cultivars, a normal-acid (Fantasia) and a low-acid (Jalousia) cultivar. The overall expression patterns of the org. acid-related genes appeared strikingly similar for the two cultivars. The genes involved in org. acid metab. showed a stronger expression in ripening fruit than during the earlier phases of development, but their expression patterns were not necessarily correlated with the changes in org. acid contents. The **tonoplast** proton pumps showed a biphasic expression pattern more consistent with the patterns of org. acid accumulation, and the **tonoplast** pyrophosphatases were more highly expressed in the fruit of the low-acid cultivar during the second rapid growth phase of the fruit.

L6 ANSWER 7 OF 42 CAPLUS COPYRIGHT 2003 ACS on STN

AB A review. Trans-membrane proton pumping is responsible for a myriad of physiol. processes including the generation of proton motive force that drives bioenergetics. Among the various proton pumping enzymes, vacuolar pyrophosphatases (V-PPases) form a distinct class of proton pumps, which are characterized by their ability to translocate protons across a membrane by using the potential energy released by hydrolysis of the phosphoanhydride bond of inorg. pyrophosphate. Until recently, V-PPases were known to be the purview of only **plant** vacuoles and plasma membranes of phototrophic bacteria. Recent discoveries of V-PPases in kinetoplastid and apicomplexan parasites, however, have expanded our view of the evolutionary reach of these enzymes. The lack of V-PPases in the vertebrate hosts of these parasites makes them potentially excellent targets for developing broad-spectrum antiparasitic agents. This review surveys the current understanding of V-PPases in parasitic protozoa with an emphasis on malaria parasites. Topol. predictions suggest remarkable similarity of the parasite enzymes to their **plant** homologs with 15-16 membrane spanning domains and conserved sequences shown to constitute crit. catalytic residues. Remarkably, malaria parasites have been shown to possess two V-PPase genes, one is an apparent orthologue of the canonical **plant** enzyme, whereas the other is a more distantly related paralogue with homol. to a recently identified new class of K⁺-insensitive **plant** V-PPases. V-PPases appear to localize both to the plasma membrane and cytoplasmic organelles believed to be acidocalcisomes or polyphosphate bodies. **Gene** transfer

expts. suggest that one of the malarial V-PPases is predominantly localized to the surface of intraerythrocytic parasites. We suggest a model in which V-PPase localized to the malaria parasite plasma membrane may serve as an electrogenic pump utilizing pyrophosphate as an energy source, thus sparing the more precious ATP. Searching for V-PPase inhibitors could prove fruitful as a novel means of antiparasitic chemotherapy.

L6 ANSWER 14 OF 42 CAPLUS COPYRIGHT 2003 ACS on STN

AB **Plant** vacuolar H⁺-translocating inorg. pyrophosphatases (V-PPases; E.C. 3.6.1.1) have been considered to constitute a family of functionally and structurally monotonous intrinsic membrane proteins. Typified by AVP1 from Arabidopsis, all characterized **plant** V-PPases share greater than 84% sequence identity and catalyze K⁺-stimulated H⁺ translocation. Here we describe the mol. and biochem. characterization of AVP2 (accession no. AF182813), a sequence-divergent (36% identical) K⁺-insensitive, Ca²⁺-hypersensitive V-**PPase** active in both inorg. pyrophosphate hydrolysis and H⁺ translocation. The differences between AVP2 and AVP1 provide the first indication that **plant** V-PPases from the same organism fall into two distinct categories. Phylogenetic analyses of these and other V-**PPase** sequences extend this principle by showing that AVP2, rather than being an isoform of AVP1, is but one representative of a novel category of AVP2-like (type II) V-PPases that coexist with AVP1-like (type I) V-PPases not only in **plants**, but also in apicomplexan protists such as the malarial parasite Plasmodium falciparum.

L6 ANSWER 18 OF 42 CAPLUS COPYRIGHT 2003 ACS on STN
AB A review with 104 refs. The H⁺-translocating inorg.
pyrophosphatase (H⁺-**PPase**) is a unique, electrogenic
proton pump distributed among most land **plants**, but only some
algae, protozoa, bacteria, and archaebacteria. This enzyme is a fine
model for research on the coupling mechanism between the pyrophosphate
hydrolysis and the active proton transport, since the enzyme consists of a
single polypeptide with a calcd. mol. mass of 71-80 kDa and its substrate
is also simple. Cloning of the H⁺-**PPase** genes from several
organisms has revealed the conserved regions that may be the catalytic
site and/or participate in the enzymic function. The primary sequences
are reviewed with ref. to biochem. properties of the enzyme, such as the
requirement of Mg²⁺ and K⁺. In **plant** cells, H⁺-**PPase**
coexists with H⁺-ATPase in a single vacuolar membrane. The physiol.
significance and the regulation of the **gene** expression of H⁺-
PPase are also reviewed.

L6 ANSWER 30 OF 42 CAPLUS COPYRIGHT 2003 ACS on STN
AB The vacuolar H+-**pyrophosphatase** (V-PPase) is an electrogenic H+ pump, which was found in the **plant** vacuolar membrane. Two **cDNA** clones (OVP1 and OVP2) encoding the V-PPase were isolated from cultured rice (*Oryza sativa*) cells and subsequently sequenced. Sequence anal. revealed that OVP1 contains 2316 nucleotides of open reading frame (ORF) and 362 nucleotides of 3'-untranslated region, whereas OVP2 comprises 2304 nucleotides of ORF and 312 nucleotides of 3'-untranslated region. The nucleotide sequences of ORF of OVP1 and OVP2 are 80.7% identical, and their 5'- and 3'-untranslated regions have 39.4 and 48.4% identity, resp. The polypeptides encoded by the ORF of OVP1 and OVP2 contain 771 and 767 amino acids, resp., and the sequences of the OVP proteins are very similar to those of other V-PPases, which are shown to have 85-91% homol. Chromosomal mapping by RFLP techniques demonstrates that OVP1 and OVP2 are isoforms encoded by different genes. Both OVP1 and OVP2 are mapped on the same chromosome (chromosome 6) to a distance of .apprx.90 cM. Northern anal. indicates that the OVP1 and OVP2 are also expressed in intact rice **plants** and OVP2 shows higher expression in calli than roots and shoots, compared to OVP1. These results show that .gtoreq.2 genes encoding the V-PPases are present in rice genome and their expressions are probably regulated in a different manner.

- AB The **tonoplast**-bound proton-translocating inorganic **pyrophosphatase** (V-type **PPase**) and the proton ATPase (V-type ATPase) are electrogenic proton pumps guaranteeing the energization of solute transport across the **tonoplast**. Using an *Arabidopsis thaliana* PCR **cDNA** fragment corresponding to clone ATAVP3 we have isolated 24 **cDNA** clones encoding **tonoplast**-bound inorganic **pyrophosphatase** of tobacco. Based on restriction analysis the **cDNA** clones could be grouped into three different classes. The complete nucleotide sequence of one member of each class (TVP5, TVP9 and TVP31) was determined. The **cDNA** clones contain an uninterrupted open reading frame of 2292 bp (TVP5), 2295 bp (TVP9) and 2298 bp (TVP31) coding for polypeptides of 764,

765 and 766 amino acids, respectively. The nucleotide sequence of the different clones is highly homologous within the **coding region** (79-89% identity) but differs strongly in the untranslated regions. The individual classes are encoded by single- or low-copy genes as judged from genomic gel blot experiments using 3'-specific probes. RNA analysis revealed that the accumulation of the specific transcripts is differentially regulated during leaf development.

- L8 ANSWER 7 OF 11 AGRICOLA Compiled and distributed by the National Agricultural Library of the Department of Agriculture of the United States of America. It contains copyrighted materials. All rights reserved. (2003) on STN DUPLICATE 1
- AB The present study was undertaken to determine whether vacuolar H⁺-**pyrophosphatase** (V-PPase) might replace vacuolar H⁺-ATPase under energy stress due to anoxia or chilling in anoxia-tolerant species such as rice (*Oryza sativa* L.) and corn (*Zea mays* L.). The relative transcript level of V-PPase in rice seedlings, like that of alcohol dehydrogenase 1, increased greatly under anoxia and declined again when the seedlings were returned to air. However, the distribution of transcripts in root, shoot, and **seed** differed somewhat from that of alcohol dehydrogenase 1. Immunoreactive V-PPase protein and V-PPase enzyme specific activity in a **tonoplast** fraction from rice seedlings increased progressively with time of anoxia or chilling at 10 degrees C, showing a 75-fold increase after 6 d of anoxia, compared with a 2-fold increase of vacuolar H⁺-ATPase activity. When the seedlings were returned to air, the specific activity returned to its initial level within 2 d. After 6 d of chilling at 10 degrees C, V-PPase specific activity reached a level 20-fold of that at 25 degrees C. In microsomes of corn roots, V-PPase specific activity did not respond to anoxia but was constitutively high. It is proposed that V-PPase can be an important element in the survival strategies of **plants** under hypoxic or chilling stress.
